Statement of Results

Definition

An integer N is said to be *powerful* if every prime factor $p \mid N$ satisfies $p^2 \mid N$.

A powerful $N \ge 1$ is a^2b^3 for $a, b \in \mathbb{Z}$ with $a, b \ge 1$, uniquely if b is squarefree.

Theorem

The smallest powerful N > 1 expressible as a sum of two coprime fourth powers is

$$N_1 := 3088257489493360278725196965477359217$$

= $17^3 \cdot 73993169^2 \cdot 338837713^2$
= $427511122^4 + 1322049209^4$,

and this is in fact the only such integer up to $3.6125 \cdot 10^{37}$.

Statement of Results (Cont'd)

Further:

- (1) We propose a candidate $\approx 1.06 \cdot 10^{60}$ for the next smallest such number, namely $17^3 \cdot 38401618921^2 \cdot 382833034044850177^2$ = $572132418369898^4 + 988478679472373^4$.
- (2) We give an algorithm using the arithmetic of elliptic curves to quickly list all such numbers with small b; use it to go up to $2^{-2/3} \exp(400) \approx 3.29 \cdot 10^{173}$.
- (3) We use (2) to propose a candidate $\approx 7.51 \cdot 10^{161}$ with b = 113 for the smallest such number with $b \neq 17$.

Introduction and Motivation

- Reconsider classical Diophantine equations with squares powerful numbers.
- ☐ Powerful numbers contain the squares as a subset of positive density $\zeta(3)/\zeta(3/2) \approx 0.46$, so might expect solutions to be more numerous only by a constant factor, but...
- ☐ New behavior can arise, e.g.
 - (1) consecutive powerful numbers, e.g. $3^2 2^3 = 17^2 2^5 3^2 = 1$ (Fermat-Pell), or
 - (2) 3-powerful "counterexamples" to FLT3, e.g. $2^3 \cdot 3^5 \cdot 73^3 = 919^3 + (-271)^3$ (use the elliptic curve $x^3 + y^3 = bz^3$).
- ☐ We search for powerful "counterexamples" to Fermat's theorem on solutions to $z^2 = x^4 + y^4$, i.e. for powerful N solutions to $N = x^4 + y^4$ with coprime $x, y \in \mathbb{Z}$.
- Expect such numbers to be rare, i.e. that the number of such $N \le N_{\text{max}}$ is $N_{\text{max}}^{o(1)}$.

Introduction and Motivation (Cont'd)

$$C_b: x^4 + y^4 = bz^2$$
 for $b \in \mathbf{Z}$, and seek coprime $(x, y, z) \in \mathbf{Z}^3$ on C_b s.t. $b \mid z$.
 \square We show that if $C_b(\mathbf{Q})$ is nontrivial, then it contains an *acceptable* point.
 \square The first twist that works is C_{17} of rank 2. The smallest soln. s.t. $17 \mid z$ is N_1 .
 \square To check that N_1 is the smallest over all b seems hard: searching over (x, y) up

to $N_1^{1/2}$ or over $b < N_1^{1/3}$ (and processing that many elliptic curves) is daunting!

Consider twists³ of the genus 1 curve $C: x^4 + y^4 = z^2$ of the form

[☐] What to do?

 $^{{}^3}$ A *twist* of a smooth projective curve C defined over a perfect field K is a smooth projective curve C' defined over K that is isomorphic to C over \overline{K} .

Why do we care?

Questions such as this one arise naturally.
This question needs a combination of nontrivial theory and computation.
It involves an application, not previously known, of a computation [1] of congruent number theta coefficients by Hart, Tornaria, and Watkins presented at ANTS-IX.
It's fun!

Reducing from $1.46 \cdot 10^{12}$ to 66551915 Candidate b's

Let N > 1 be powerful and a sum of two coprime fourth powers. Then:

- (1) Every $p \mid N$ is 1 mod 8.
 - *Proof Sketch*: $2 \nmid N$ and odd $p \mid N \Rightarrow \exists \alpha \in (\mathbb{Z}/p)^*$ s.t. $\alpha^4 = -1$.
- (2) (Lucas) If $N = a^2b^3$ and b squarefree, then $a, b \ge 17$.

 Proof Sketch: We have b > 1 by Fermat. If a = 1, then $x^2 \pm iy^2 \in \mathbf{Z}[i]$ are cubes. Reduce to showing $y^2 = x^3 + \{12, 108\}x$ have rank 0.

Let b be a product of $k \ge 1$ distinct primes, each 1 mod 8, and $C_b : x^4 + y^4 = bz^2$.

- (1) If $C_b(\mathbf{Q}) \neq \emptyset$, then C_b is **Q**-isomorphic to its Jacobian $E_b: Y^2 = X^3 4b^2X$.
- (2) The rational torsion of E_b is $E_b(\mathbf{Q})_{\text{tors}} = E_b[2] = {\infty, (0,0), (\pm 2b,0)}.$
- (3) C_b has nontrivial rational point $\Leftrightarrow E_b$ has positive rank $\Leftrightarrow 2b$ is congruent,
- (4) in which case, by Coates-Wiles [2], E_b has positive *analytic* rank, and this can be checked via Tunnell's criterion [3].

Reducing from $1.46 \cdot 10^{12}$ to 66551915 Candidate b's (Cont'd)

□ Going up to b ≤ M can be used to find all solutions up to 17²M³.
 □ The list of all such numbers (more precisely, of all b such that E_b has even positive analytic rank) up to M = 5 · 10¹¹ is included in the results of a recent comptuation [1] by Hart, Tornaria, and Watkins.⁴

Look at squarefree $b \ge 1$ with each factor 1 mod 8 such that 2b is congruent.

☐ This leaves us with 66551915 "candidate b" values, and looking at these suffices to go up to $17^2(5 \cdot 10^{11})^3 = 3.6125 \cdot 10^{36} > N_1$.

⁴We thank Mark Watkins and William Hart for making this list available to us.

Principal Search Strategy

Let $b \ge 1$ be as above and look for coprime $x, y, z \in \mathbf{Z}$ s.t. $x^4 + y^4 = bz^2$.

- (1) Factor $x^4 + y^4 = (x^2 + iy^2)(x^2 iy^2)$. Then $x^2 \pm iy^2 \in \mathbf{Z}[i]$ are coprime.
- (2) Write $x^2 + iy^2 = \beta \zeta^2$ for $\beta, \zeta \in \mathbf{Z}[i]$ primitive of norms b, z respectively.
- (3) Let $\beta = \mu + i\nu$ and $\zeta = r + is$ for $\mu, \nu, r, s \in \mathbf{Z}$ with $\gcd(\mu, \nu) = \gcd(r, s) = 1$. We are reduced to the conics

$$x^2 = Q_1(r,s) := \mu(r^2 - s^2) - 2\nu rs,$$

 $y^2 = Q_2(r,s) := 2\mu rs + \nu(r^2 - s^2).$

If b has k prime factors, then (up to units) there are 2^k primitive $\beta \in \mathbf{Z}[i]$ of norm b. For each β , look at the two conics.

- (1) If either conic is locally obstructed, discard β .
- (2) Else, parametrize $x^2 = Q_1(r,s)$ by $\mathbf{P}_{\mathbf{O}}^1$ using $r, s, x \in \mathbf{Z}[m,n]_2$, BUT...
- (3) Not sufficient. If $m, n \in \mathbb{Z}$, then $gcd(m, n) = 1 \not\Rightarrow gcd(r(m, n), s(m, n)) = 1$.

Interlude: Integer Parametrizations of Planar Integer Quadratic Forms

- \square Let $Q(r,s,x) \in \mathbf{Z}[r,s,x]_2$ s.t. the conic $C_Q = \mathbf{V}(Q) \subset \mathbf{P}^2$ is rational.
- □ Usually, a single parametrization $(r, s, x) \in \mathbb{Z}[m, n]_2^3$ does not suffice to list all coprime triples $(r, s, x) \in \mathbb{Z}^3$ on Q by using only coprime $m, n \in \mathbb{Z}^2$.
- ☐ For instance, let $Q = x^2 r^2 s^2$. This admits the parametrization $(r,s,x) = (m^2 n^2, 2mn, m^2 + n^2)$, but can't get $(4,3,5) \in \mathbb{Z}^3$ on Q by $m,n \in \mathbb{Z}$.
- □ We show: there is a finite list $\{(r_i, s_i, x_i)\}_i \subset \mathbf{Z}[m, n]_2^3$ of parametrizations s.t. for every pairwise coprime triple $(r, s, x) \in \mathbf{Z}^3$ satisfying Q there is at least one i and some coprime $m, n \in \mathbf{Z}$ such that $(r, s, x) = (r_i(m, n), s_i(m, n), x_i(m, n))$.

Proof Sketch: For each prime $\ell \mid \operatorname{disc} Q$, there is a finite set I_ℓ of parametrizations in $\mathbf{Z}_\ell[m,n]_2$ corresponding to the ℓ -adic components of Q. These parametrizations (r_i,s_i,x_i) are indexed by $i\in \prod_{\ell\mid \operatorname{disc} Q} I_\ell$.

Elkies has written a gp routine qsolve that given a quadratic form Q produces such a list (r_i, s_i, x_i) of parametrizations.

Principal Search Strategy (Cont'd)

- (4) Produce a finite list $\{(r_i(m,n), s_i(m,n), x_i(m,n))\}_i$ of parametrizations of the plane conic $x^2 = O_1(r,s)$ as above.
 - □ In our case, disc $Q_1 = 4(\mu^2 + \nu^2) = 4b$, so $|I_2| = 1$ and $|I_\ell| = 2$ for odd $\ell \mid b$, so 2^k parametrizations suffice.
- (5) For each *i*, let $\Psi_i(m,n) = Q_2(r_i(m,n),s_i(m,n))$. A point (x,y,z) as above then gives us a point on the elliptic curve $Y^2 = \Psi_i(T,1)$ for some *i*.
- (6) Have strategy: find all β , find all (r_i, s_i, x_i) , and all points on $Y^2 = \Psi_i(T, 1)$ using Stoll's hyperellratpoints up to a calculated height bound.

This strategy sufficed to prove the theorem.

Another Strategy for Small b's

- □ For a $b \ge 1$ as above, consider the 2-isogenous $E_b': Y^2 = X^3 + b^2X$ which admits a map $\rho_b: C_b \to E_b', (x:y:z) \mapsto (b(x/y)^2, b^2xz/y^3)$.
- \square Algorithm: for each $b \ge 1$,
 - (i) find all $P \in E_b'(\mathbf{Q})$ with $\hat{h}(P) \le \frac{1}{2} \log N_{\text{max}} + \frac{1}{3} \log 2$, and
 - (ii) for each P = (X, Y) check if $X/b \in (\mathbf{Q}^*)^2$. If not, discard P.
 - (iii) Else, write $\sqrt{X/b} = x/y$ for coprime $x, y \in \mathbb{Z}$ and let $z := Yy^3/(b^2x)$.
 - (iv) For (x, y, z) as in (iii), check if $b \mid z$.
- \square We show: the set of acceptable points in $E_b'(\mathbf{Q})$ forms a coset of a subgroup of $E_b'(\mathbf{Q})$ of index dividing $2^k b$.

Proof Sketch: $\rho_b(C_b(\mathbf{Q})) = w_2^{-1}[b]$ where $w_2 = [X] : E_b'(\mathbf{Q}) \to \mathbf{Q}^*/(\mathbf{Q}^*)^2$. For $p \mid b$, curve $E_b'(\mathbf{Q}_p)$ has Kodaira type I_0^* and Tamagawa number $c_p = 4$; using this, figure out when a point is p-acceptable.

- □ Given gens. P_1, \dots, P_r of $E'_b(\mathbf{Q})$ /tors, a $P = \sum_{i=1}^r a_i P_i \in E'_b(\mathbf{Q})$ is acceptable iff the $a_i \in \mathbf{Z}$ satisfy a few linear congruences mod 2 and mod p for each $p \mid b$.
- \square Given generators of $E'_h(\mathbf{Q})$, can list all acceptable points up to any height.

Another Strategy for Small *b*'s (Cont'd)

The BSD conjecture and heuristics on L(E, s) at s = 1 suggest that the regulators of E_h, E'_h grow not faster than $b^{1/2+o(1)}$. \square Our curves have rank ≥ 2 , so their MW groups would be typically generated by points of height at most $b^{1/4+o(1)}$. \Box Can't find generators of $E_b'(\mathbf{Q})$ for a typical $b < 5 \cdot 10^{11}$, but a 2-descent in mwrank [4] sufficed to find the full MW group for most "small" b (i.e. $b < 10^4$). \square Since $(0,0) \in E_h'(\mathbf{Q})[2]$, mwrank easily found all principal homogenous spaces. \Box For 67 of the 72 candidate $b < 10^4$ (all except 4721, 4777, 6497, 6577, and 9881), mwrank found 2 independent points in $E'_{h}(\mathbf{Q})$ and proved that they together with torsion (0,0) generate $E'_h(\mathbf{Q})$. \Box This allowed us to go up to $2^{-2/3} \exp(400)$ for all but five $b < 10^4$ to find the other solutions mentioned on the results page.

Suggestions for Further Work

To take our analysis beyond $3.6125 \cdot 10^{37}$, we would need either

- \square an extension of the Hart-Tornaria-Watkins [1] computation to $2b > 10^{12}$, or
- \square an extension of Lucas's result on $x^4 + y^4 = a^2b^3$ to a = 17, 41, 73, ..., or
- a complete parametrization of coprime (X, y, b) such that $X^2 + y^4 = a^2b^3$ (as in Roberts [5] for a = 1) by homogenous polynomials of degree 12.

To take our second approach further, we would need

□ to find a better way (say using higher descent) of finding generators of the MW group of E'_b : $Y^2 = X^3 + b^2X$, at least in the fairly special case when b > 1 is a product of distinct primes, each 1 mod 8, with 2b congruent.
